Epics and user-stories

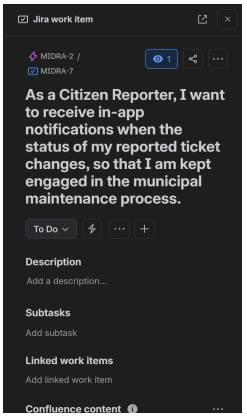

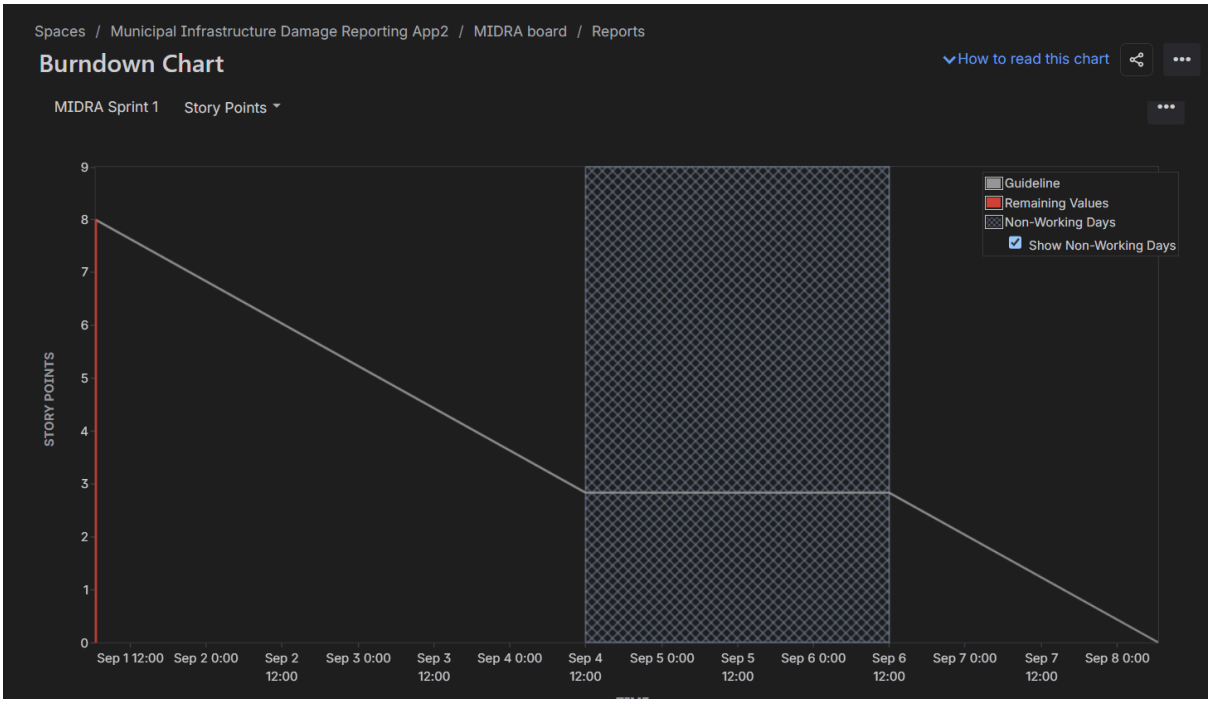

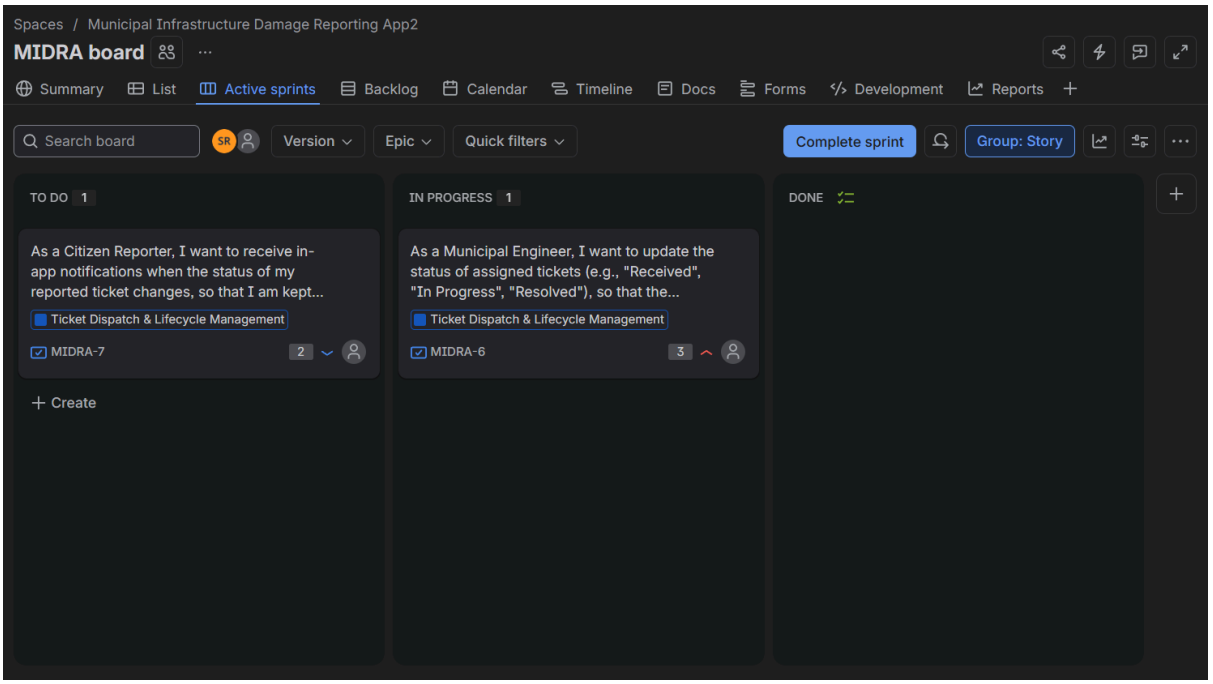

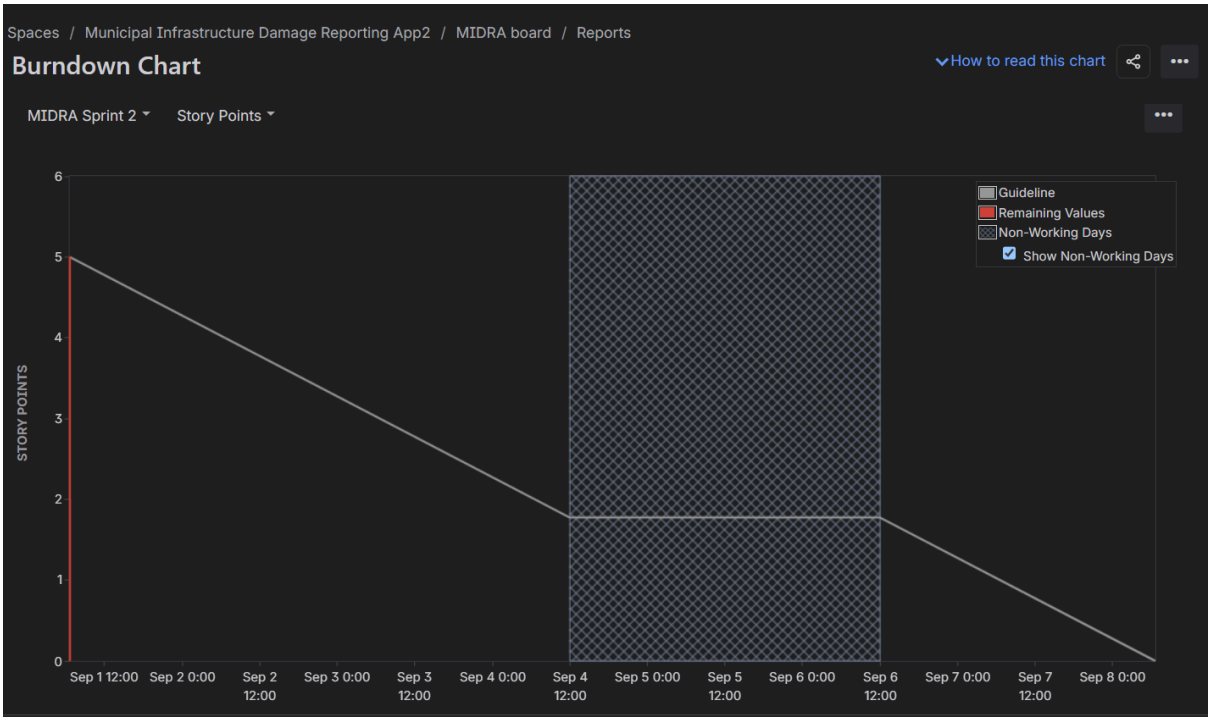

Sprint 1 burnout chart

Sprint 2 sprint board and burnout chart

Reflection Questions Analysis

1. Did your estimations reflect the actual effort?

Yes, utilizing the Fibonacci sequence provided a highly realistic scale for comparing task complexity. For instance, assigning a higher value (e.g., 5 points) to the automated GPS metadata extraction (Story 1.1) accurately reflected its backend technical difficulty compared to the straightforward frontend effort of an in-app notification (Story 2.3, estimated at 2 points). This relative sizing made estimating much more accurate than guessing hours.

2. Was your backlog well-prioritized?

The backlog prioritization was effective because it strictly followed business value and core functionality. High-priority requirements—like automated ticket dispatch (Story 2.1) and GPS extraction (Story 1.1)—were positioned at the top of the sprint. This ensured the fundamental mechanics of the Municipal Reporting App were addressed before secondary features like fallback map pins (Story 1.2, Medium priority) or status notifications (Story 2.3, Low priority).

3. How did your simulated sprint align with your plan?

The simulated sprint aligned directly with the initial sprint plan. Moving the user stories across the Kanban board (To Do → In Progress → Done) provided immediate visual confirmation of the workflow. Breaking down the larger Epics into specific, bite-sized User Stories ensured that no single task bottlenecked the "In Progress" column for too long.

4. What insights did the burndown chart give about your team's capacity?

The burndown chart visually demonstrated our team's velocity—the exact rate at which we complete story points. Because tasks were moved to "Done" steadily throughout the simulation, the chart showed a consistent, healthy downward slope. It confirmed that the total number of story points committed to Sprint 1 perfectly matched the team's capacity for that timebox, with no scope creep or unfinished leftover tasks.
